

Chemistry 6A Fall 2007

Dr. J. A. Mack

Monday

9/17/07

Chem. 6A This week:

Lab: Experiment **2** (*You will need goggles!!*)

Lecture: Chapter 2

No goggles, no lab!
No open toed shoes allowed!
No pre-lab, no lab!
No excuses!

It's time to play...

Name that Element!

Cs cesium

Hg Mercury

Zn zinc

As Arsenic

It's time to play...

Name that compound!

MgCl₂ magnesium chloride

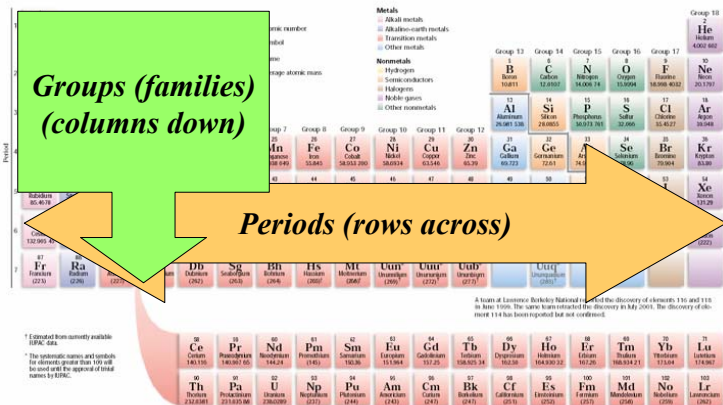

CuSO₄ copper (II) sulfate

calcium acetate Ca(C₂H₃O₂)₂

hydrogen hydroxide HOH

or water... H₂O

The modern periodic table is defined by:

9-17-07

CSUS Chem 6A F07 Dr. Mack

7

The Periods are labeled:

9-17-07

CSUS Chem 6A F07 Dr. Mack

8

The Groups are labeled:

9-17-07

CSUS Chem 6A F07 Dr. Mack

The discovery of modern atomic structure:

Experiments!

9-17-07

CSUS Chem 6A F07 Dr. Mack

19

Rutherford's Scattering Experiment: 1911

9-17-07

CSUS Chem 6A F07 Dr. Mack

20

Rutherford's Experiment: Explained

- Most of the α -particles passed through the gold foil.
- Some α -particles were deflected slightly as they came close to the nucleus by the + charge repulsion.
- Some were deflected backwards by direct collisions with the nucleus.

Conclusion:

- Atoms are mostly space.
- The nucleus carries most of the mass with a positive charge.

9-17-07

CSUS Chem 6A F07 Dr. Mack

21

The Composition of an Atom:

The atom is mostly empty space

- protons and neutrons in the nucleus.
- the number of electrons is equal to the number of protons.
- electrons in space around the nucleus.

9-17-07

CSUS Chem 6A F07 Dr. Mack

23

Further experiments lead to the discovery and characterization of the electron, proton and neutron.

Electron:
-1 charge

J.J. Thompson cathode ray tube (1897)
electrons were negatively charged

R. Millikan Oil drop experiment (1909)
charge on the electron

Proton:
+1 charge

E. Rutherford (1918)
hydrogen nucleus termed a "proton"

Neutron:
no charge

J. Chadwick (1932)
neutral particle with the mass of a proton

9-17-07

CSUS Chem 6A F07 Dr. Mack

24

Atomic Number, Z

An element's identity is defined by the number of protons in the nucleus: Z

13	←	Atomic number
Al	←	Atom symbol
26.981	←	Atomic weight

Isotopes, Atomic Numbers, and Mass Numbers

- Atomic number (Z) = number of protons in the nucleus.
- Mass number (A) = total number of nucleons in the nucleus (i.e., protons and neutrons).
- One nucleon has a mass of 1 amu
(*Atomic Mass Unit*) a.k.a “*Dalton*”
- Isotopes have the same Z but different A .
- The elements are arranged by Z on the periodic table.

By convention, for element X, we write A_ZX

The isotope ${}^{75}_{34}\text{Se}$ is used medically for diagnosis of pancreatic disorders. How many protons, neutrons, and electrons does an atom of ${}^{75}_{34}\text{Se}$ have?

75 protons +
neutrons

34 protons

protons = 34

electrons = 34

neutrons = $75 - 34 = 41$

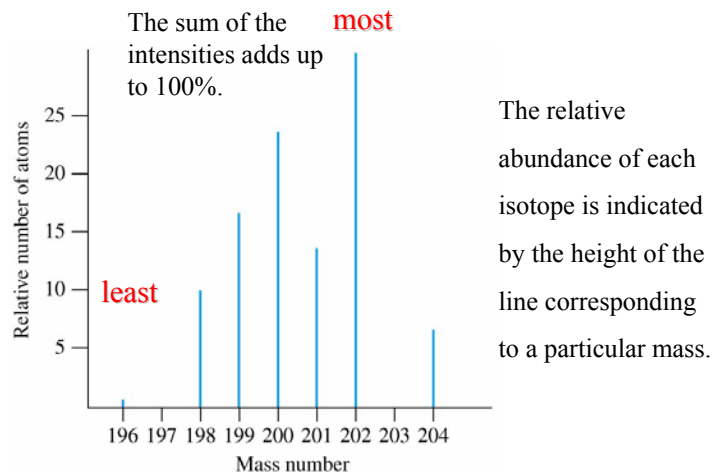

Atomic Masses and the Periodic Table:

In nature, an element is found to contain a mixture of all of the naturally occurring isotopes.

These isotopes occur in proportions represented by their *natural abundances*.

As macroscopic beings, we measure matter on a “bulk” scale (many atoms).

The *fraction or abundance* of each of the individual isotopes statistically weights the average atomic mass of an element.

9-17-07

CSUS Chem 6A F07 Dr. Mack

29

Example:

Chlorine has two isotopes:

Cl-35 & Cl-37 *shorthand notation*

Each isotope occurs in nature with a specific mass and corresponding fraction or "**Percent Abundance**".

1 u = 1 amu

9-17-07

CSUS Chem 6A F07 Dr. Mack

30

The **average weighted** atomic mass is determined by the following mathematical expression:

$$m \text{ Cl (u)} = m \text{ Cl-35} \times \frac{\text{fraction that are Cl-35}}{\text{abundance of Cl-35}} + m \text{ Cl-37} \times \frac{\text{fraction that are Cl-37}}{\text{abundance of Cl-37}}$$

$$= 34.96885\text{u} \times 0.7553 + 36.96590 \times 0.2447 = 35.45 \text{ u}$$

(4 sig. fig)

This is the value that is reported on the periodic table.

Note that: $0.7553 + 0.2447 = 1.0000$ (100%)

9-17-07

CSUS Chem 6A F07 Dr. Mack

31

Avogadro's Number and the Mole

The concept of a mole is defined so that we may equate the amount of matter (mass) to the number of particles (mole).

The Standard is based upon the C-12 isotope.

The atomic mass of ${}^{12}\text{C}$ is defined as exactly 12 u.

The atomic mass of ${}^{12}\text{C}$ is 1.99265×10^{-23} g.

$$1 \text{ amu} = (\text{the mass of one } {}^{12}\text{C atom} \div 12) = 1.66054 \times 10^{-24}\text{g}$$

$$= 1.66054 \times 10^{-27} \text{ kg}$$

9-17-07

CSUS Chem 6A F07 Dr. Mack

32

Avagadro's Number

Since one mole of ^{12}C has a mass of 12g (exactly), 12g of ^{12}C contains 6.022142×10^{23} ^{12}C -atoms.

But carbon exists as 3 isotopes: C-12, C-13 & C-14

The average atomic mass of carbon is 12.011 u.

From this we conclude that 12.011g of carbon contains 6.022142×10^{23} C-atoms

Is this a valid assumption?

Yes, since N_A is so large, the statistics hold.

Molar Masses

Since we can equate mass (*how much matter*) with moles (*how many particles*) we now have a **conversion factor** that relates the two.

$$\text{mols} \times \text{molar mass (g/mol)} = \text{grams}$$

The Molar Mass of a substance is the amount of matter that contains one-mole or 6.022×10^{23} particles.

aka: Avogadro's number (N_A)

The atomic masses on the Periodic Table also represent the molar masses of each element in grams per mole (g/mol)

So if you have 12.011g of carbon...

you have 6.022×10^{23} carbon atoms!

So if you have 39.95g of argon...

you have 6.022×10^{23} argon atoms!

if you have a mole of dollar bills... you are Bill Gates...

you have 6.022×10^{23} bucks!

and if you have 6.022×10^{23} avocados...

you have...

a "guacamole"
